

Assumptions:

1. The front end will send all requests in json format.
2. The front end will receive and be able to handle all responses in json format.
3. The front end will have to make sure all requests are passed in with correct structure, casing, parameters etc.
4. Because this is a test with limited scope, some validations (such as making sure id is a number) can be bypassed.
5. The front end will pass in the whole object on all adds and updates. If they only want to update one field, they will still pass in the whole object with all of the old values and the new one
6. No duplicate ids in either file.

Scrum Master Questions

1. Why are we doing this with static files? A db seems much more in order.
